■ ABSTRACT

Introduction and Aims: Fibroblast growth factor 23 (FGF-23) induces phosphaturia. Its clinical impact is beyond mineral bone disease in chronic kidney disease (CKD), being coupled with vascular calcification and mortality. Residual renal function (RRF) is associated with significant capacity to excrete phosphate in peritoneal dialysis (PD). Besides testing whether FGF-23 is still related with glomerular filtration rate (GFR) and phosphate excretion in this late stage of CKD (5d), we aimed to explore its link with vascular calcification.

Subjects and Methods: FGF-23 (C terminal) was measured in forty prevalent PD patients with RRF, aged 61.5 (51.0-67.0) years old, in renal replacement therapy (RRT) for 43.5 (23-80.0) months; 36.6% were female, 19.5% had diabetes *mellitus* and 37.5% were under automated PD regimen; 80% were on PD first, and only 20% had previous RRT. Relevant variables including dietary phosphate (P) intake, CKD- bone laboratory parameters, serum 25-hydroxyvitamin D, magnesium (Mg) levels, GFR, urinary phosphate, fractional excretion of phosphorus (FEP), albumin, proBNP and Adragão vascular calcification score were explored.

Results: Median levels (25-75% range) of serum variables were: FGF-23 1997 (1623-2149) RU/mL, Mg 0.94 (0.8-1.0) mmol/L, 25-hydroxyvitamin D 30 (18-47) nmol/L, calcium 2.2 (2.0-2.37) mmol/L, phosphorus 1.69 (1.30-1.90) mmol/L, PTH 429 (309-626) pg/mL. FGF-23 correlated positively with serum phosphate ($r = 0.39$, $p = 0.013$) and negatively with urine volume ($r = -0.48$, $p = 0.001$), phosphaturia ($r = -0.594$, $p < 0.0001$) and GFR ($r = -0.61$, $p < 0.0001$). However, FGF-23 was not significantly correlated with age, total time of RRT, dietary P, FEP, Mg, nor 25-hydroxyvitamin D. High FGF-23 group had higher FEP. GFR was the single independent predictor of increased FGF-23. On the other hand, neither FGF-23 nor low FEP/FGF-23 ratio were significantly associated with the vascular calcification score. Only albumin (lower), magnesium (lower) and proBNP (higher) levels significantly differed in calcified versus non-calcified patients (all with $p < 0.05$).

Conclusions: In our population, FGF-23 was not associated with vascular calcification. GFR was the single independent predictor of increased FGF-23 in patients with diuresis. Increment of FGF-23 in PD patients

signalizes an active endocrine phosphaturic process compensating renal function loss, as expressed by higher fractional excretion of phosphorus. It alerts for dietetic and therapy optimization. However, its link with vascular calcification still lacks validation.

Key-Words: FGF-23; fractional excretion of phosphorus; peritoneal dialysis; phosphaturia; residual renal function; vascular calcification.

RESUMO

Introdução: O fator de crescimento do fibroblasto 23 (FGF-23) induz fosfatúria. A sua importância clínica ultrapassa o seu impacto na doença óssea da doença renal, associando-se, segundo alguns autores, à calcificação vascular e à mortalidade. Nos doentes em diálise peritoneal (DP), a função renal residual (FRR) é responsável por uma fracção significativa da excreção do fósforo. O nosso objectivo foi testar se o FGF-23 se relaciona com o débito do filtrado glomerular (DFG) e a excreção de fosfato nesta fase tardia da DRC(5d), focando a sua relação com calcificação vascular. **Métodos:** O FGF-23 (C terminal) foi medido em 40 doentes prevalentes em DP com função renal residual, com idade de 61,5 (51,0-67,0) anos, em tratamento substitutivo da função renal há 43,5 (23-80,0) meses. Destes doentes, 36,6% eram do sexo feminino 19,5 % tinham diabetes *mellitus* e 37,5% estavam sob regime de DP automática; 80% iniciaram diálise com DP; apenas 20% estiveram previamente sob outra técnica substitutiva da função renal. Foram exploradas variáveis clínicas relevantes, nomeadamente fosfato dietético, parâmetros ósseos, 25-hidroxivitamina D, magnésio (Mg), DFG, fosfatúria, fracção excrecional de fosfato (FEP), albumina, proBNP e o score de calcificação vascular de Adragão. **Resultados:** Os valores medianos (IQ 25-75) das variáveis séricas foram: FGF-23 1997 (1623-2149) RU/mL, Mg 0,9 (0,8-1,0) mmol/L, 25-hidroxivitamina D 30 (18-47) nmol/L, cálcio 2,2 (2,0-2,4) mmol/L, fósforo 1,7 (1,3-1,9) mmol/L, PTH 429 (309-626) pg/mL. O FGF-23 correlacionou-se positivamente com o fósforo sérico ($r = 0,39, p = 0,013$) e negativamente com o volume de urina ($r = -0,48, p = 0,001$), fosfatúria ($r = -0,594, p < 0,0001$) e DFG ($r = -0,61, p < 0,0001$). No entanto, não se verificou qualquer relação significativa com idade, tempo em terapêutica da substituição da função renal, fósforo dietético, FEP, Mg ou 25-hidroxivitamina D. O grupo com valor elevado de FGF-23 apresentava aumento da FEP. O DFG foi preditor independente de aumento do FGF-23. Por outro lado, nem o FGF-23 nem o rácio baixo FEP/FGF-23 se associaram significativamente com o score de calcificação vascular. A albumina (baixa), o magnésio (baixo) e o proBNP (elevado) foram significativamente diferentes em doentes calcificados quando comparados com não calcificados (todos com $p < 0,05$). **Conclusões:** No nosso estudo não foi confirmada a associação do FGF-23 com a calcificação vascular. O DFG foi o único preditor independente do aumento de FGF-23 em doentes sob diálise peritoneal com função renal residual. O aumento do FGF-23 sinaliza um processo fosfatúrico ativo, compensatório face à perda de FRR, tal como é expresso pelo aumento da fracção excrecional de fósforo. Poderá alertar para oportuna optimização da dieta e da terapêutica no âmbito do metabolismo fosfocálcico. No entanto a sua associação com calcificação vascular permanece por validar.

Palavras-Chave: Calcificação vascular; diálise peritoneal; FGF-23; fosfatúria; fracção excrecional de fósforo; função renal residual.

INTRODUCTION

Fibroblast growth factor -23 (FGF-23) is a hormone whose main known function is the regulation of the phosphate concentration in plasma. It is secreted by osteocytes and acts on the kidneys, at the FGF receptor (FGFR)-klotho complex, to increase the excretion

of phosphate. The FGF-23 also inhibits the conversion of calcidiol (25[OH] vitamin D) to calcitriol (1.25[OH]₂ vitamin D)¹. According with these actions, FGF-23 induces phosphaturia and is responsible for a significant part of phosphate metabolism and control². In CKD, as urinary phosphate excretion declines FGF-23 levels increase and can reach 1000-fold above

normal in end stage renal disease (ESRD)³. In recent years, an association was reported between FGF-23 and all-cause mortality, not only in people undergoing dialysis⁴, but also in pre-dialysis patients⁵.

Hyperphosphatemia often occurs in dialysis patients and is an independent risk factor for arterial calcification, associated with cardiovascular events and mortality⁶. Residual renal function (RRF) is responsible for a significant capacity to excrete phosphate, therefore, FGF23 seems to be a key mediator of serum phosphorus levels control in patients with diuresis. However, the role for FGF-23 in the process of progressive arterial calcification is not clear⁷.

Since the clinical impact of high FGF-23 appears to be beyond mineral bone disease in CKD, its measurement may identify a different dimension of kidney function that is not fully captured by glomerular filtration rate. Therefore, besides testing whether FGF-23 is still related with GFR and phosphate excretion in this late stage of CKD (5d), we aimed to explore its link with vascular calcification.

SUBJECTS AND METHODS

Study population:

We have studied 40 prevalent and stable patients aged 18 years or older who had been undergoing chronic peritoneal dialysis (continuous ambulatory peritoneal dialysis or continuous cyclic peritoneal dialysis) at the division of Nephrology at Centro Hospitalar do Porto, Portugal.

Inclusion criteria: To be included in the study the patients had to be on PD for at least 3 months and have residual renal function (as measured by diuresis > 100mL/day). The clinical characteristics and laboratory data of our 40 patients treated with peritoneal dialysis are summarized in Table I.

Data collection and measurements:

We have analysed the following data that was collected at a single random visit to the peritoneal dialysis centre: demographic characteristics,

Table I

Clinical characteristics and laboratory data of participants

	Patients (n = 40)
Female sex	36.6%
Diabetes <i>mellitus</i>	19.5%
Automated peritoneal dialysis (APD)	37.5%
Treatment	
Vitamin D analogues	85.0%
Calcium carbonate	31.7%
Sevelamer	63.4%
Cinacalcet	29.3%
Age (years)	61.5 (51.0 – 67.0)
Time on PD (months)	43.5 (23.0 – 80.0)
Magnesium (mmol/L)	0.94 (0.85 – 1.0)
25-hydroxyvitamin D (nmol/L)	30 (18 – 47)
Calcium (mmol/L)	2.2 (2.0 – 2.37)
Phosphate (mmol/L)	1.69 (1.30 – 1.90)
PTH (pg/mL)	429 (309 – 626)
Albumin (g/L)	4.01 (3.78 – 4.22)
ProBNP (pg/mL)	1637 (556 – 4358)
Urine volume (mL)	1000 (537-1400)
Urine phosphate (mmol/day)	6.21 (4-11.47)
FEP (%)	64 (54-79)
GFR (mL/min)	3 (0.9-5.6)

medical history, smoking status, use of active vitamin D analogues, cinacalcet or oral phosphate binders, dose of dialysis, GFR, and blood and urinary samples. Comprehensive metabolic panels and urinary biochemical panels were measured using standard assays. A dietary inquiry was done and the ingested daily amount of phosphate was calculated. The peritoneal clearance of phosphate was measured.

Urinary fractional excretion of phosphate (FEP) was calculated as follows: [urine phosphorus (mg/dl)/serum phosphorus (mg/dl)] × [serum creatinine (mg/dl)/urine creatinine (mg/dl)] × 100.

Plasma FGF-23 was measured using the second generation C-terminal assay. Samples were immediately centrifuged, aliquoted, and stored at -80 °C until batched assays were performed. We have also applied the Adragão vascular calcification score⁸ at 32 patients after excluding those who missed appointment for radiological testing. Adragão *et al.*⁸ showed that vascular calcification score ≥3 is the best cut-off value associated with cardiovascular mortality and cardiovascular events, reason why we used that value to dictate a positive vascular score. All tests and radiographic films of pelvis and hands

were performed and blindly classified with Adragão score by a single investigator, at Centro Hospitalar do Porto, Portugal.

Statistical analysis:

We used standard descriptive statistics to assess clinical and laboratory data at baseline. Continuous variables were summarized as median and interquartile range (IQR). Categorical variables were expressed as frequencies and proportions. All variables were explored cross-sectionally. Pearson or Spearman correlations were used as appropriate. Mann-Whitney U test was used to investigate variables in subgroups.

The FGF-23 variable was categorized as FGF-23 tertile (below or above 1800 RU/ml) and investigated by multivariable logistic regression. For all comparisons, a p -value < 0.05 was considered statistically significant.

RESULTS

Associations of demographic, clinical, and laboratory characteristics with FGF-23:

The median concentration and IQ₂₅₋₇₅ of immunoreactive FGF-23 was 1997 (1623 – 2149) reference units (RU/ml).

The FGF-23 correlated positively with serum phosphate ($r = 0.39$, $p = 0.011$) and negatively with urine volume ($r = -0.48$, $p = 0.002$), phosphaturia ($r = -0.594$, $p < 0.0001$) and GFR ($r = -0.57$, $p < 0.0001$). However FGF-23 was not significantly correlated with age, time on dialysis, dietary phosphate ingestion, FEP, Mg, nor 25-hydroxyvitamin D.

We present the variables in subgroups categorized according to FGF-23 30% tertile (Table II).

The high FGF-23 levels group presented significantly lower GFR, higher serum phosphate and higher urinary fractional excretion of phosphate (Fig. 1).

Multivariable logistic regression showed that GFR was the sole independent predictor of FGF-23. Each 1 ml/min decrease in GFR was associated with a 90% chance of having higher FGF-23 (OR 1.898 (1.226-2.939), $p = 0.004$).

FGF-23 and arterial calcification

Radial and digital calcifications were present in 19 patients (59.4%) and iliac and femoral calcifications were present in 21 patients (65.6%).

The distribution of vascular calcification score in the 32 patients was the following: score 0 in nine patients (28.1%), score 1 in one patient (3.1%), score 2 in four patients (12.5%), score 3 in seven

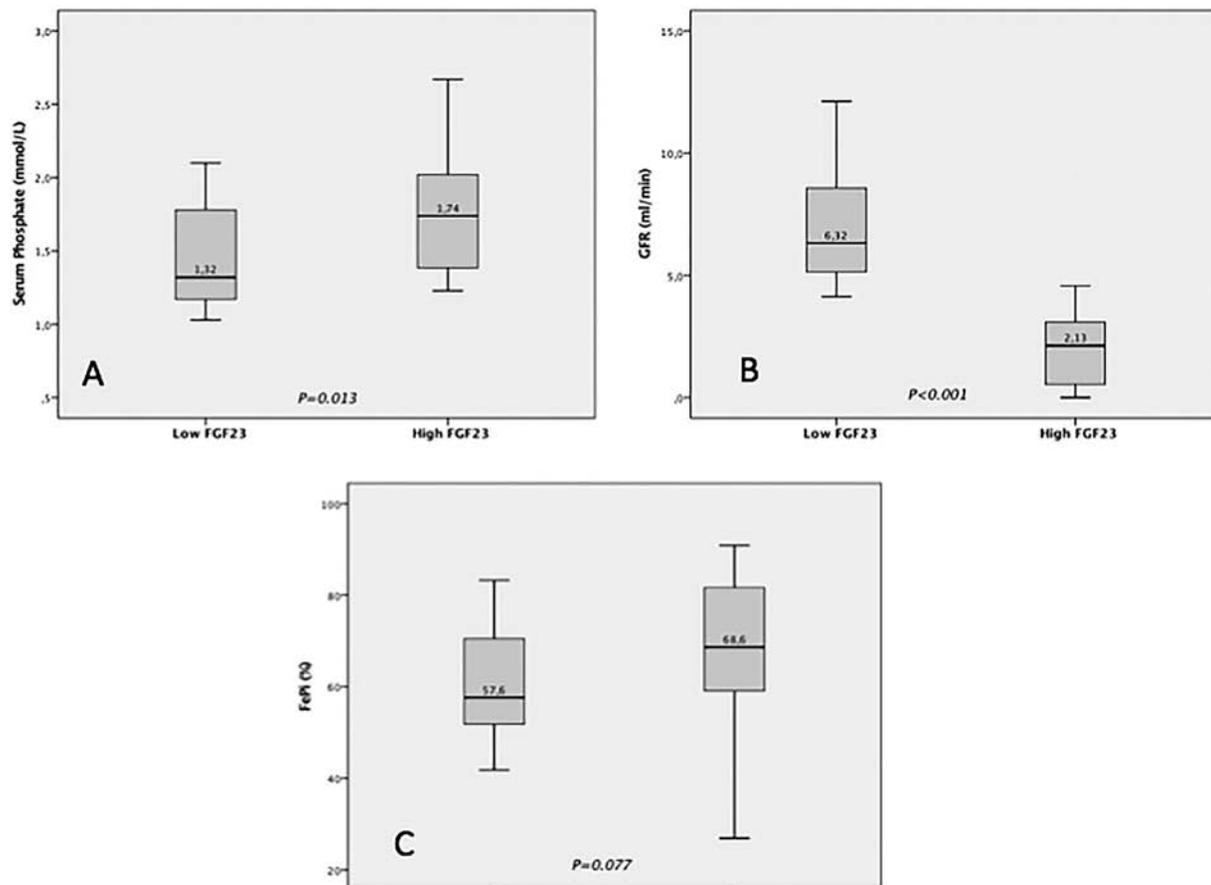

Table II

Clinically relevant variables between high (> 1800 RU/ml) versus low (< 1800 RU/ml) FGF-23 groups

	Low FGF-23 n = 12	High FGF-23 n=28	p-value
Age (years)	63.0 (58.0-66.8)	60.5 (48.5-69.5)	0.478
Time on dialysis (months)	43.5 (17.8-293.8)	43.5 (24.8-74.8)	0.941
Diet P (mg/day)	1044 (905-1490)	1233(1032-1389)	0.61
Serum phosphate (mmol/L)	1.32 (1.17-1.79)	1.74 (1.38-2.03)	0.013
Urine volume (mL)	1450 (1300-2375)	700 (400-1175)	<0.001
Phosphaturia (mmol/day)	13.32 (7.25-18.16)	4.99 (1.85-7.35)	<0.001
FEP %	57.6 (51.3-71.9)	68.6 (58.2-82.2)	0.077
GFR (ml/min)	6.33 (4.99-9.18)	2.14 (0.53-3.14)	<0.001
Mg (mmol/L)	0.90 (0.85-0.96)	0.98 (0.84-1.05)	0.101
25-hydroxyvitamin D (nmol/L)	30.0 (17.0-31.0)	30.5 (18.0-51.8)	0.593
PTH (pg/mL)	446.0 (327.3-521.7)	418.4 (284.3-690.8)	0.836
Peritoneal P clearance (L/week)	28 (25.7-38)	36.5(32.4-43)	0.09

Figure 1

Graphical presentation of clinically significant variables distribution in subgroups according to the 30% tertile of FGF23: higher (> 1800 RU/mL) vs. lower (< 1800 RU/mL) FGF 23 groups (A – serum phosphate; B – GFR; C – fractional excretion of phosphorus).

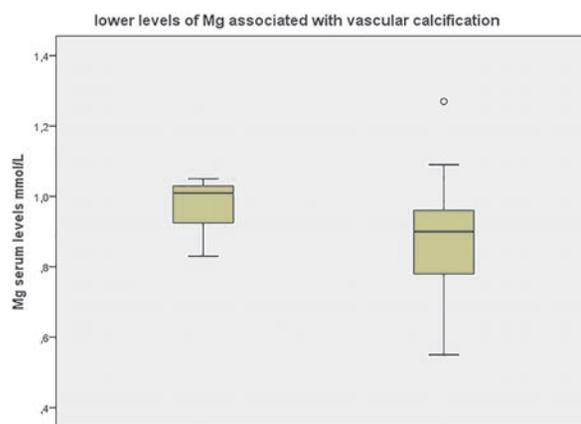

patients (22.0%), score 4 in five patients (15.6%), score 5 in one patient (3.1%), score 6 in three patients (9.4%) and score 7 and 8 both in one patient (each 3.1%).

The comparison between patients with positive vascular calcification score (score ≥ 3) versus low calcified patients showed that FGF-23 and low FEP/FGF-23 were not significantly associated with vascular calcification.

By exploring subgroups with the Mann-Whitney U test only albumin (lower levels, $p = 0.046$), pro-BNP (higher levels, $p = 0.005$) and magnesium (lower levels, $p = 0.026$) significantly differed between calcified (score ≥ 3) versus non-calcified group of patients (Fig. 2).

Figure 2

Graphical presentation of differences of magnesium levels between calcified (score ≥ 3) vs. non-calcified group of patients

■ DISCUSSION

The results of this cross-sectional study confirm that FGF-23 levels are markedly elevated in patients with ESRD and are associated with hyperphosphatemia, but were not associated with vascular calcification. Previous studies sustain the use of FGF-23 as a stable biomarker of disordered phosphate metabolism⁹. Our study also showed that lower GFR determine higher FGF-23 levels. Indeed the amount of FGF-23 increases dramatically in dialysis patients. Data on FGF-23 levels in patients undergoing PD is limited. Isakova *et al.*⁹ showed that among PD adults with residual renal function, there is a continuous relationship between higher FGF-23 and lower residual renal function. However, we did not find any association between dialysis vintage and higher FGF-23. The limited number of patients that had previous RRT comparing to those on PD first (80%) did not allow to reliably test if FGF23 is significantly increased in patients with previous haemodialysis course of time.

There is still a lack of understanding on the determinants of FGF-23 serum concentrations. This issue was recently revised by the Frazão group¹⁰ and dietary phosphate has been pointed as a putative predictor. We were unable to document a significant difference in ingested phosphate load between the groups, but our population had high phosphate ingestion (1000-1400 mg/day), above the recommended target of 800-1000 mg/day, effacing the opportunity to test this hypothesis. This, however, remains a relevant issue in a population of dialysis patients prone to progressively loose renal capability to excrete ingested phosphate load. However, the phosphaturic action of FGF-23 is signaled by the higher phosphate fractional excretion present in the high FGF-23 group.

In early CKD progression FGF-23 is elevated well before serum phosphate levels are increased¹¹ and is not correlated with PTH. The FGF-23 also presents a more stable laboratory profile and less intra-individual variability than PTH¹² being an opportune tool to signalize the patient who may benefit from dietary counseling, dialysis optimization or higher dose of phosphate chelating agents.

We have also showed that therapy was adequately adjusted to increase dialysis solute removal

since peritoneal phosphate clearance was higher in patients with lower renal function. Additionally, we tested the link between FGF-23 and vascular calcification. A low fractional excretion of phosphate/FGF-23 ratio has been associated with severe abdominal aortic calcification in stage 3 and 4 CKD¹³. But, in our population FGF-23 or low fractional excretion of phosphate/FGF-23 ratio were not significantly associated with a positive vascular calcification score: the modest sample of patients may have limited the ability to demonstrate significant differences between calcified versus non-calcified groups. However, the results published in literature for vascular calcification also remain conflicting^{7, 14}.

Interestingly our results suggest an association of hypomagnesemia and vascular calcification, as previously documented by other investigators¹⁵ pointing that hypomagnesemia and high FGF-23 levels were independent predictors of mitral valve calcification and intima-media-thickness in 150 diabetic patients with mild to moderate CKD. It is stated that magnesium antagonizes phosphate-induced apoptosis of vascular smooth muscle cells preventing vascular calcification and it was shown that magnesium modifies the association between serum phosphate and the risk of progression to end-stage kidney disease in patients with non-diabetic chronic kidney disease¹⁶. The cellular pathways of magnesium interference with vascular calcification are presently under investigation¹⁷.

We acknowledge some limitations in our study, particularly dependent on the small sample of enrolled patients and the cross-sectional design. Methodological skills also need to be optimized since the measurement of FGF-23 is still investigational: the reagents in 2nd generation human FGF-23 ELISA kit have been optimized, so that the high dose "hook effect" is not a problem for samples with elevated FGF-23 values. Samples with levels between the highest standard and 750,000 RU/mL will read greater than the highest standard and were diluted 1:10 or greater with the 0 RU/mL calibrator. But dilution of high-reading samples with saline may result in significant deviation from linearity. Besides current ELISA kits for plasma intact FGF-23 measurement show poor analytical agreement and cannot be used interchangeably¹⁸.

There is a scarce number of studies addressing the pathophysiological axis of FGF-23 in peritoneal

dialysis, therefore, it seems to us that the present study is opportune and points to investigational tracks such as the link between magnesium and vascular calcification. Longitudinal design will be mandatory to clarify other putative determinants of FGF-23 and its ultimate clinical impact on PD patients.

■ CONCLUSIONS

Fibroblast growth factor 23 was not associated with vascular calcification in our population. Glomerular filtration rate was the single independent predictor of increased FGF-23 on PD patients with significant RRF. Increment of FGF-23 in PD patients signals an active endocrine phosphaturic process compensating renal function loss as expressed by higher fractional excretion of phosphorus. It alerts for dietetic and therapy optimization. However, its link with vascular calcification still lacks validation.

Conflicts of interest statement: None declared.
