Esophageal neuroendocrine carcinomas are aggressive rare tumors, aggressive and with poor prognosis, most of them seem to be effective.

We report 5 cases of neuroendocrine carcinoma of the esophagus, diagnosed between the years 2012-2015 with approximately 300 cases described in the literature, and at this time only obtained by multivisceral resection. Objective: To present 3 cases of pancreaticoduodenectomy (PD) in patients with advanced gastric adenocarcinoma.

**MATERIAL E MÉTODOS:** Materials and methods: Among 1000 patients operated between August 1997 and April 2016, only three cases underwent PD (0.3%). In those cases we evaluated: operative blood loss, transfusion, operatory time, morbidity, hospitalization time, stage and survival.

**RESULTADOS:** Results: 3 patients have been analyzed, as age between 44 and 56 years, karnofsky 100-90%. All cases was advanced gastric cancer T4B, 2(66%) was lymph node stage’s positive and just 1(33%) was negative. Operation time ranged between 360, at 6 hours with just one patient had need of blood transfusion. All 3 cases presented a pancreatic fistula. Hospitalization time ranged between 13 to 40 days. And the 5 year’s survival was 100%, but 1 case cannot be evaluated.

**DISCUSSÃO:** Conclusions: the PD is a rare and safe procedure in patients with good performance status with GA. It provides a good survival with acceptable rates of morbidity.

**RESUMO:** Pancreatoduodenectomy in Advanced Gastric Adenocarcinoma

**OBJETIVO:**

**INTRODUÇÃO:** Introduction:The pancreaticoduodenectomy (PD) in advanced gastric adenocarcinoma (GA) is a rare procedure because the indications are extremely restricted and the high morbidity and mortality lead this kind of surgery to be performed only in young and with high performance status (PS) patients. The pancreas is involved in up to 50% of advanced cases, an R0 resection of gastric cancer in essential to achieve long-term survival, and at times this can only be obtained by multivisceral resection. Objective: To present 3 cases of pancreaticoduodenectomy (PD) in patients with advanced gastric adenocarcinoma.

**MATERIAL E MÉTODOS:** Materials and methods: Among 1000 patients operated between August 1997 and April 2016, only three cases underwent PD (0.3%). In those cases we evaluated: operative blood loss, transfusion, operatory time, morbidity, hospitalization time, stage and survival.

**RESULTADOS:** Results: 3 patients have been analyzed, as age between 44 and 56 years, karnofsky 100-90%. All cases was advanced gastric cancer T4B, 2(66%) was lymph node stage’s positive and just 1(33%) was negative. Operation time ranged between 360, at 6 hours with just one patient had need of blood transfusion. All 3 cases presented a pancreatic fistula. Hospitalization time ranged between 13 to 40 days. And the 5 year’s survival was 100%, but 1 case cannot be evaluated.

**DISCUSSÃO:** Conclusions: the PD is a rare and safe procedure in patients with good performance status with GA. It provides a good survival with acceptable rates of morbidity.
